

Assignment – 3.1

2303A51599

PROMPT :-

Generate a Python function that checks whether a given number is a palindrome.

CODE and OUTPUT :-

The screenshot shows a code editor window with a dark theme. The code is written in Python and defines a function named `is_number_palindrome`. The function takes a single parameter, `number`, which is expected to be an integer. The function returns a boolean value indicating whether the number is a palindrome. The code uses string manipulation to reverse the number and compare it with the original. The code editor interface includes tabs for PROBLEMS, OUTPUT, DEBUG CONSOLE, TERMINAL, and PORTS. Below the code, the terminal output shows the function being tested with various numbers, including negative ones, and the results are printed as True or False.

```
AI-3.1.py > is_number_palindrome
1  #generate a Python function that checks whether a given number is a palindrome.
2  def is_number_palindrome(number):
3      """
4          Check if a given number is a palindrome.
5
6          A number is a palindrome if it reads the same forwards and backwards.
7
8          Parameters:
9          number (int): The number to check.
10
11         Returns:
12         bool: True if the number is a palindrome, False otherwise.
13         """
14
15         # Convert the number to string to easily reverse it
16         str_number = str(number)
17
18         # Compare the string with its reverse
19         return str_number == str_number[::-1]
20         cleaned_s = ''.join(char.lower() for char in s if char.isalnum())
21         return cleaned_s == cleaned_s[::-1]
22
23     # Example Usage:
24     print(is_number_palindrome(121)) # True
25     print(is_number_palindrome(-121)) # False
26     print(is_number_palindrome(10)) # False
27     print(is_number_palindrome(12321)) # True
28     print(is_number_palindrome(1234321)) # True
```

PROBLEMS 2 OUTPUT DEBUG CONSOLE TERMINAL PORTS

True
False
False
True
True
○ PS D:\AI>
```

Justification :-

In zero-shot prompting, the model receives only the problem statement without any supporting examples. This checks the AI's basic understanding of the concept. While generating a palindrome-checking function, the AI typically uses simple logic such as reversing the number or converting it into a string. However, due to the lack of constraints or examples, the solution may ignore important edge cases like negative values, single-digit numbers, or

invalid inputs. This indicates that although zero-shot prompting works well for simple tasks, it may not produce fully robust or real-world-ready code without additional guidance.

Task 2: One-Shot Prompting:-

PROMPT :

Generate a Python function to compute the factorial of a given number.

Example: Input: 5 → Output: 120.

CODE and OUTPUT :

```
29 #generate a Python function to compute the factorial of a given number. Example: Input: 5 → Output: 120.
30 def compute_factorial(n):
31     """
32     Compute the factorial of a given number.
33
34     The factorial of a non-negative integer n is the product of all positive integers less than or equal to n.
35
36     Parameters:
37     n (int): The number to compute the factorial for.
38
39     Returns:
40     int: The factorial of the number.
41     """
42     if n < 0:
43         raise ValueError("Factorial is not defined for negative numbers.")
44     elif n == 0 or n == 1:
45         return 1
46     else:
47         factorial = 1
48         for i in range(2, n + 1):
49             factorial *= i
50         return factorial
51
52 # Example Usage:
53 print(compute_factorial(5)) # Output: 120
54 print(compute_factorial(0)) # Output: 1
55 print(compute_factorial(1)) # Output: 1
56 print(compute_factorial(7)) # Output: 5040
```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL PORTS Python Debug Console + ×

```
● PS D:\AI> & 'c:\Users\aaq\AppData\Local\Programs\Python\Python314\python.exe' 'c:\Users\aaq\vscode\extensions\ms-python.python\3.12.0-win32-x64\bundled\libs\debugpy\launcher' '60726' '--' 'D:\AI\AI-3.1.py'
120
1
1
5040
○ PS D:\AI>
```

Justification :

One-shot prompting provides the AI with one example along with the task description. The given example (Input: 5 → Output: 120) helps the model clearly understand the expected result and logic. Compared to zero-shot prompting, this approach leads to more accurate implementations with correct looping or recursion. The presence of a single example reduces ambiguity and improves correctness, showing that even minimal guidance can significantly enhance the quality of AI-generated code.

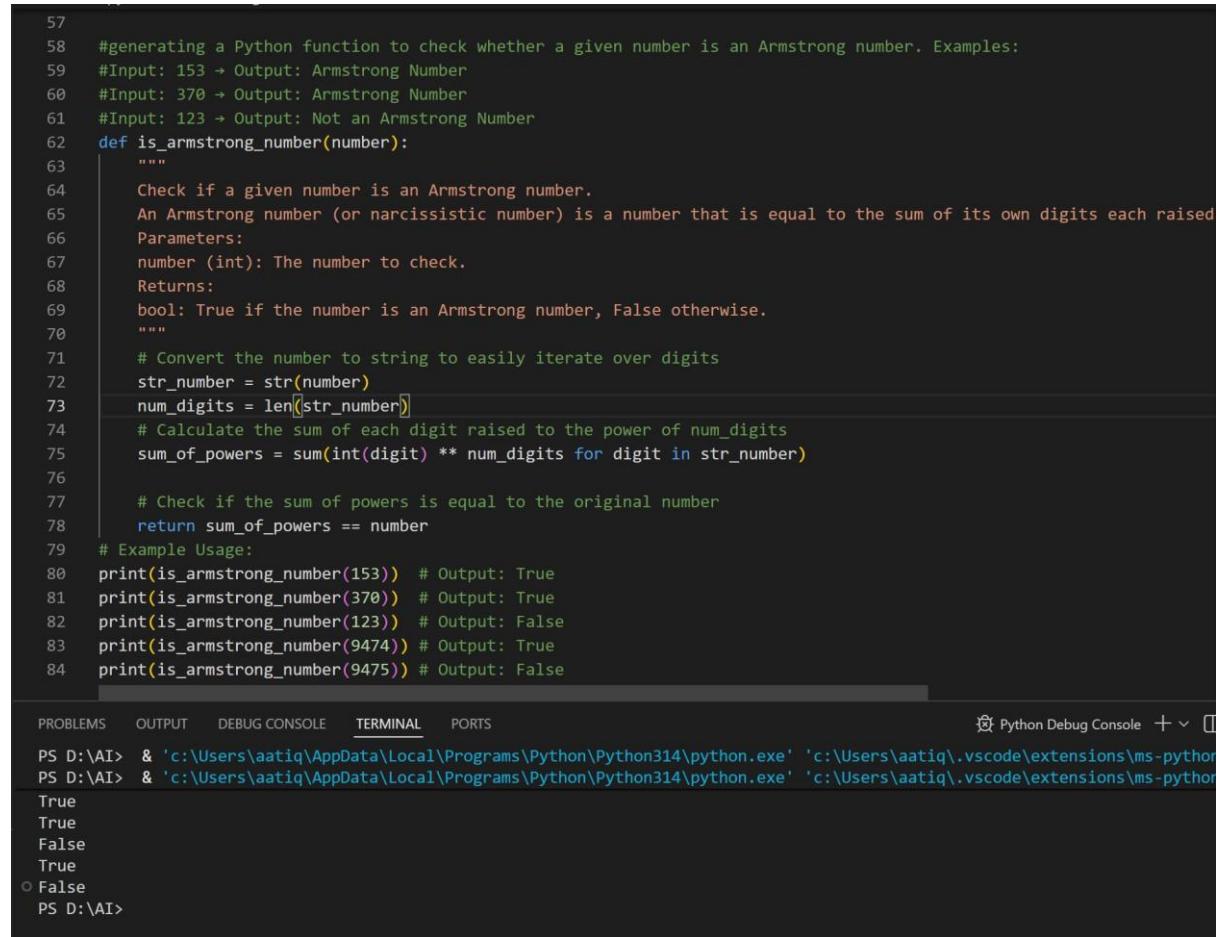

Task 3: Few-Shot Prompting (Armstrong Number Check):-

PROMPT :

Generating a Python function to check whether a given number is an Armstrong number. Examples:

- Input: 153 → Output: Armstrong Number
- Input: 370 → Output: Armstrong Number
- Input: 123 → Output: Not an Armstrong Number

CODE and OUTPUT :

```
57
58     #generating a Python function to check whether a given number is an Armstrong number. Examples:
59     #Input: 153 → Output: Armstrong Number
60     #Input: 370 → Output: Armstrong Number
61     #Input: 123 → Output: Not an Armstrong Number
62     def is_armstrong_number(number):
63         """
64             Check if a given number is an Armstrong number.
65             An Armstrong number (or narcissistic number) is a number that is equal to the sum of its own digits each raised
66             Parameters:
67                 number (int): The number to check.
68             Returns:
69                 bool: True if the number is an Armstrong number, False otherwise.
70             """
71             # Convert the number to string to easily iterate over digits
72             str_number = str(number)
73             num_digits = len(str_number)
74             # Calculate the sum of each digit raised to the power of num_digits
75             sum_of_powers = sum(int(digit) ** num_digits for digit in str_number)
76
77             # Check if the sum of powers is equal to the original number
78             return sum_of_powers == number
79
80     # Example Usage:
81     print(is_armstrong_number(153))  # Output: True
82     print(is_armstrong_number(370))  # Output: True
83     print(is_armstrong_number(123))  # Output: False
84     print(is_armstrong_number(9474)) # Output: True
85     print(is_armstrong_number(9475)) # Output: False
```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL PORTS Python Debug Console + ⌂

```
PS D:\AI> & 'c:\Users\aaatiq\AppData\Local\Programs\Python\Python314\python.exe' 'c:\Users\aaatiq\.vscode\extensions\ms-python.vscode-pyright\lib\python\__init__.py'
PS D:\AI> & 'c:\Users\aaatiq\AppData\Local\Programs\Python\Python314\python.exe' 'c:\Users\aaatiq\.vscode\extensions\ms-python.vscode-pyright\lib\python\__init__.py'
True
True
False
True
False
PS D:\AI>
```

Justification :

Few-shot prompting includes multiple examples, which strongly influences how the AI interprets the problem. By seeing both Armstrong and non-Armstrong cases, the model better understands digit extraction, power calculations, and decision-making logic. This results in cleaner, more structured, and mathematically accurate code. Additionally, the AI performs better when handling different test cases. Overall, providing several examples improves reliability and reduces logical mistakes, making the solution more suitable for real-world use.

Task 4: Context-Managed Prompting (Optimized Number Classification):-

PROMPT :

Generate an optimized Python program that classifies a number as prime, composite, or neither.

Task:

- Ensure proper input validation.
- Optimize the logic for efficiency.

CODE and OUTPUT :

The screenshot shows a VS Code interface with a dark theme. A code editor window displays a Python file named 'AI-3.1.py'. The code defines a function 'classify_number' that takes an integer 'num' and returns a string indicating whether it is 'Prime', 'Composite', or 'Neither'. The code includes input validation for non-integer inputs and handles negative numbers. It uses a loop to check divisibility from 3 up to the square root of 'num'. The code is annotated with comments explaining its purpose and logic. Below the code editor, a terminal window shows the command used to run the script and the resulting output: 'PS D:\AI> & 'c:\Users\aaatiq\AppData\Local\Programs\Python\Python314\python.exe' 'c:\Users\aaatiq\.vscode\extensions\ms-python'.0-win32-x64\bundled\libs\debugpy\launcher' '62266' '--' 'D:\AI\AI-3.1.py''. The terminal then lists the classification results for various numbers: '● Prime', 'Composite', 'Neither', and 'Neither'.

```
AI-3.1.py > classify_number
87 #generate an optimized Python program that classifies a number as prime, composite, or neither. Task:
88 #Ensure proper input validation.
89 #Optimize the logic for efficiency.
90 def classify_number(num):
91     """Classify a number as prime, composite, or neither.
92     Parameters:
93         num (int): The number to classify.
94     Returns:
95         str: "Prime", "Composite", or "Neither".
96     # Input validation
97     if not isinstance(num, int):
98         return "Input must be an integer."
99     if num < 0:
100        return "Neither"
101    if num == 0 or num == 1:
102        return "Neither"
103    # Check for primality
104    if num == 2:
105        return "Prime"
106    if num % 2 == 0:
107        return "Composite"
108
109    for i in range(3, int(num**0.5) + 1, 2):
110        if num % i == 0:
111            return "Composite"
112    return "Prime"
113 # Example Usage:
114 print(classify_number(11)) # Output: Prime
115 print(classify_number(15)) # Output: Composite
116 print(classify_number(1)) # Output: Neither
117 print(classify_number(0)) # Output: Neither
```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL PORTS Python Debug Console + ×

```
PS D:\AI> & 'c:\Users\aaatiq\AppData\Local\Programs\Python\Python314\python.exe' 'c:\Users\aaatiq\.vscode\extensions\ms-python'.0-win32-x64\bundled\libs\debugpy\launcher' '62266' '--' 'D:\AI\AI-3.1.py'
● Prime
Composite
Neither
Neither
```

Justification :

Context-managed prompting supplies detailed instructions, constraints, and performance expectations. By specifying input validation, efficiency requirements, and classification rules, the AI produces a well-optimized and complete program. The generated solution correctly handles special cases such as 0, 1, and negative numbers, and applies efficient logic by checking divisibility only up to \sqrt{n} . Compared to simpler prompting techniques, this method results in professional-quality, optimized, and reliable code, highlighting the importance of clear context for complex tasks.

Task 5: Zero-Shot Prompting (Perfect Number Check):-

PROMPT :

Generate a Python function that checks whether a given number is a perfect number.

CODE and OUTPUT :

```
119 #generate a Python function that checks whether a given number is a perfect number.
120 def is_perfect_number(number):
121     """
122         Check if a given number is a perfect number.
123 
124         A perfect number is a positive integer that is equal to the sum of its proper positive divisors, excluding itself.
125 
126         Parameters:
127             number (int): The number to check.
128 
129         Returns:
130             bool: True if the number is a perfect number, False otherwise.
131         """
132         if number <= 0:
133             return False
134 
135         # Calculate the sum of proper divisors
136         sum_of_divisors = 0
137         for i in range(1, number // 2 + 1):
138             if number % i == 0:
139                 sum_of_divisors += i
140 
141         # Check if the sum of divisors equals the original number
142         return sum_of_divisors == number
143 
144 # Example Usage:
145 print(is_perfect_number(6))    # True
146 print(is_perfect_number(28))    # True
147 print(is_perfect_number(12))    # False
148 print(is_perfect_number(496))    # True
```

PROBLEMS OUTPUT DEBUG CONSOLE TERMINAL PORTS Python Debug Console

```
● PS D:\AI> & 'c:\Users\aaatiq\AppData\Local\Programs\Python\Python314\python.exe' 'c:\Users\aaatiq\.vscode\extensions\ms-python.python_0.10.0\lib\site-packages\debugpy\launcher' '51384' '--' 'D:\AI\AI-3.1.py'
True
True
False
True
○ PS D:\AI>
```

Justification :

In this zero-shot scenario, the AI depends entirely on its prior knowledge to generate the solution. The code usually identifies divisors and calculates their sum correctly. However, it may include inefficiencies such as checking all numbers up to n or failing to validate non-positive inputs. This demonstrates that while zero-shot prompting can generate functional code, it often lacks optimization and thorough validation. Therefore, it is better suited for basic demonstrations rather than efficient or production-level solutions.

Task 6: Few-Shot Prompting (Even or Odd Classification with Validation):-

PROMPT :

Generating a Python program that determines whether a given number is even or odd, including proper input validation.

Examples:

- Input: 8 → Output: Even
- Input: 15 → Output: Odd

- Input: 0 → Output: Even

CODE and OUTPUT :

```

149  #generating a Python program that determines whether a given number is even or odd, including proper input validation
150  #Examples:
151  #Input: 8 → Output: Even
152  #Input: 15 → Output: Odd
153  #Input: 0 → Output: Even
154  def check_even_odd(number):
155      """
156          Determine whether a given number is even or odd.
157
158          Parameters:
159          number (int): The number to check.
160
161          Returns:
162          str: "Even" if the number is even, "Odd" if the number is odd.
163          """
164
165          # Input validation
166          if not isinstance(number, int):
167              return "Input must be an integer."
168
169          # Check if the number is even or odd
170          if number % 2 == 0:
171              return "Even"
172          else:
173              return "Odd"
174
175  print(check_even_odd(8))    # Output: Even
176  print(check_even_odd(15))   # Output: Odd
177  print(check_even_odd(0))    # Output: Even
178  print(check_even_odd(-4))   # Output: Even

```

The screenshot shows the VS Code interface with the Python Debug Console tab selected. The terminal window displays the following output:

```

● PS D:\AI> & 'c:\Users\aaqiq\AppData\Local\Programs\Python\Python314\python.exe' 'c:\Users\aaqiq\.vscode\extensions\ms-python.python-0.0-win32-x64\bundled\libs\debugpy\launcher' '51813' '--' 'D:\AI\AI-3.1.py'
Even
Odd
Even
Even

```

Justification :

Few-shot prompting, supported by multiple examples including edge cases like zero, helps the AI clearly understand expected behavior and output formatting. The generated program typically includes proper conditional checks, clear messages, and better handling of negative numbers. Compared to zero-shot approaches, the solution also performs better when dealing with invalid or unexpected inputs. This confirms that providing multiple examples improves robustness, accuracy, and clarity in AI-generated programs.
